DISSOLVED NUTRIENT AND SUSPENDED PARTICULATE MATTER DATA FOR
THE SAN FRANCISCO BAY ESTUARY, CALIFORNIA,
OCTOBER 1991 THROUGH NOVEMBER 1993

By Stephen W. Hager

ABSTRACT

The U.S. Geological Survey conducted hydrologic investigations in San Francisco Bay between October of 1991 and November of 1993. Dissolved inorganic plant nutrients, nitrate, nitrite, ammonium, silica, and reactive phosphorus were measured in surface and in near-bottom waters at previously established locations in both northern and southern reaches of the bay. Salinity, turbidity, and concentrations of suspended particulate matter also were measured. Additionally, concentrations of dissolved organic nitrogen and phosphorus were occasionally measured in the spring of 1992. This report presents the sampling and analytical methods, and the data from these studies. Data on the variability due to sampling and sample handling procedures, on the precision of the analytical methods, and on recoveries of known additions from samples are also presented.

INTRODUCTION

As part of a continuing study of the San Francisco Bay estuary, cruises were conducted between October 1991 and November 1993 (table 1). The main objectives of these cruises were to examine the effects of different amounts of freshwater inflow to the bay on phytoplankton dynamics, and thus on the concentrations of the dissolved plant nutrients (nitrite, nitrate, ammonium, reactive phosphorus, silica, organic nitrogen and organic phosphorus). Sampling during this period of variable freshwater inflow will enable comparisons with data collected during the preceding drought and with other "normal" inflow periods. Salinity and concentrations of suspended particulate matter and turbidity in the surface waters were also routinely measured. The basic hydrologic data for these cruises are given by Wienke and others (1992, 1993), and Caffrey and others (1994).

This report presents the sampling and analytical methods used for these studies and the data.

METHODS

Data were collected at previously established stations throughout the bay (table 2, fig. 1). At each station, a two-liter sample for dissolved nutrients and suspended particulate matter (SPM) was collected from the vessel's bow pump, simultaneously with the lowering of sensors for conductivity, temperature and depth (CTD, Sea-Bird Electronics model 9/11). Because the bow intake of the R.V. Polaris is about 1.5 meters below the surface, salinities calculated from conductivity and temperature (using Sea-Bird software) for the 1.5- to 2.5-meter interval (2-meter CTD salinities) are usually presented in this report. For stations at which the CTD either was not used or at which there was some malfunction, salinities were estimated from the linear regression of the CTD values for that cruise and readings averaged over one minute intervals from a continuous, on-line, inductive salinometer. Details of the pumping system and the on-line salinometer are found in a report by Schemel and Dedini (1979). As a check on the adequacy of this sampling protocol, salinity bottles also were routinely taken from the bulk nutrient/SPM sample. These samples were analyzed in the laboratory using an Autosal 8400A salinometer. Where available, the bottle salinities are reported. Salinity is given in practical salinity units (psu; Lewis, 1980).

The abundance of light scattering constituents in the water, referred to here as turbidity, was measured by a Turner Designs Model 10 fluorometer, fitted with an on-line nephelometry flow cell. Data were averaged over one minute intervals. Turbidity data are unitless in the data tables.

Concentrations of SPM were determined gravimetrically. An aliquot of water from either the nutrient sample or a Niskin bottle sample (as noted in the data tables) was vacuum filtered through a preweighed, 47 mm-diameter, 0.45 μm pore-size, Nuclepore, polycarbonate, membrane filter. The filter was air dried for a minimum of 2 days, then reweighed. After additional drying time, weighings were repeated until there was agreement between consecutive weighings. Weights were corrected for the weight of residual salt on the filter on the basis of

experiments where small quantities of previously filtered saltwater of known salinity were filtered.

Samples for dissolved inorganic nutrient analysis were filtered within 15 minutes of sampling through 47 mm diameter, 0.4 μm pore-sized, Nuclepore, polycarbonate, membrane filters under vacuum (less than 14 kPa). Filtered samples were stored in 30 mL, high-density polyethylene bottles (Nalgene 2002-0001), that had been rinsed with acetone, and then rinsed with and stored filled with a 2.5 meq/L solution of sodium bicarbonate. These samples were refrigerated from the time of processing until analysis the next morning, except that the samples from the first day of a two day cruise (see table 1) were refrigerated for an extra day.

Duplicate samples for dissolved organic nutrients were gravity filtered within a half hour of sampling through Gelman type A/E glass fiber filters. Aliquots of filtrate were then placed in quartz irradiation tubes. Later, in the laboratory, 0.3 mL of 800 meq/L sodium bicarbonate solution was added to samples with salinities greater than 10 psu, and 10 mL of concentrated artificial seawater (approximately 140 psu, four times the concentrations used by Strickland and Parsons, 1968, p. 76) to samples with salinities less than 10 psu. Just prior to irradiation, 0.1 mL of 30 percent hydrogen peroxide was added to each sample. Samples were irradiated for 6 hours in a La Jolla Scientific Model PO-14 ultra-violet irradiator. Samples were decanted into 30 mL high-density polyethylene bottles for analysis.

Concentrations of ammonium (NH_4), nitrate plus nitrite ($\text{N}+\text{N}$), nitrite (NO_2), dissolved reactive phosphate (DRP), and dissolved silica (DSi) were measured simultaneously on a Technicon AutoAnalyzer II system. Analyzer responses were usually linear over the ranges of concentrations encountered in this study. Blanks and single concentration upscale standards were analyzed at two- to four-hour intervals. Standards were prepared in artificial river water (1.0 meq/L solution of sodium bicarbonate) and artificial seawater (Strickland and Parsons (1972, p. 76), except for NH_4 , for which natural seawater was used. The analyzer was maintained at constant temperature by circulating 37°C water through tubes inserted through the centers of the glass mixing coils on each manifold.

The NH_4 method uses a 0.8 mL/min sample pump tube to which is added 0.23 mL/min salicylate reagent (140 g sodium salicylate and 0.90 g sodium nitroferricyanide to 1 L of distilled water), and 0.32 mL/min air. Immediately thereafter, 0.42 mL/min of oxidizing/complexing reagent (200 mL of stock solution [90 g sodium citrate dihydrate and 6 g sodium hydroxide to 1 L of distilled water], 0.120 g sodium dichloroisocyanurate and 8 drops of Brij-35 surfactant) is added. Following a ten turn mixing coil, the stream enters the 37°C heating bath, followed by two 20-turn coils thermostatted at 37°C. The stream then passes through a 10-turn coil at room temperature before entering the colorimeter. Absorbance is determined at 630 nm in a 15 mm flowcell. Blanks vary non-linearly with salinity and were estimated using a six-point calibration curve consisting of mixtures of natural seawater and artificial river water (0, 20, 40, 60, 80, 100 percent). This method is preliminary, and was based primarily on work by Verdouw and others (1978) and Bower and Holm-Hansen (1980).

The $\text{N}+\text{N}$ method was the Technicon (1973) method number 100-70W with one twenty-turn coil added to increase reaction time for better color stability. Copper sulfate (0.121 g per 20 liters) was added to the

ammonium chloride reagent, as suggested by Connors and Beland (1976). The pH of this reagent was not adjusted. Preparation of cadmium for the reduction columns was similar to that described by Wood and others (1967). A second order curve fitted using four standards spaced over the expected range of the sample concentrations was used to calculate concentrations of N+N when concentrations exceeded 80 μM . Nitrate can be calculated by subtracting the corresponding concentration of NO₂ from the results of this analysis.

The NO₂ method was an adaptation of the Technicon (1973) method number 100-70W with the cadmium column removed.

The DSi method was a modification of the Technicon (1976) method number 105-71W. The acid-molybdate reagent was diluted and its flow rate increased, keeping the acid- and molybdate-to-sample ratios unchanged. Additional mixing coils were added to give more complete color development.

The method for DRP was a modification of that of Atlas and others (1971), using ascorbic acid (70 g plus 50 mL acetone per liter of solution) as a reductant. To increase reaction time for maximum color development, ten-turn coils replaced the five-turn coils and a twenty-turn coil replaced the ten-turn coil in the manifold design.

For dissolved organic nitrogen and phosphorus (DON and DOP), the irradiated samples were analyzed for N+N, NH₄ and DRP using the methods above. The sum of the N+N and NH₄ measurements on the irradiated sample, corrected for appropriate blanks, is the total dissolved nitrogen (TDN) concentration. The DON concentration is the difference between TDN and the dissolved inorganic nitrogen (DIN = N+N plus NH₄ on the un-irradiated sample) concentration. The DOP concentration is the total dissolved phosphorus (TDP = DRP on the irradiated sample) concentration minus the DRP (un-irradiated) concentration.

Sample from the cruise of August 26, 1992 were frozen soon after filtration, and stored frozen at -20°C. At least 14 hours before analysis, samples were removed from the freezer and allowed to thaw at room temperature. After being shaken twice, they were analyzed as above, on September 30, 1992.

FACTORS AFFECTING THE QUALITY OF THE DATA

Sampling Error

Nutrient as a function of salinity plots are important to an understanding of the behavior of the nutrients in the estuary. Because the ordinary sampling protocol for the nutrient and SPM samples was to begin sampling as near as possible (+/- 1/2 minute) to the CTD measurements and to use the 2-meter CTD salinity value as the salinity of the sample, comparison of bottle salinities with 2-meter CTD salinities is used as a check on the adequacy of this protocol. In other words, the degree of agreement between the 2-meter CTD salinity and the bottle salinity indicates the amount of the scatter in nutrient / salinity plots that can be expected due to sampling error.

The results are shown in figures 2a and 2b, plotted as the difference between the 2-meter CTD salinity and the corresponding bottle salinity versus the bottle salinity, for the northern and southern parts of San Francisco Bay, respectively. The 2-meter CTD values appear to be slightly higher on the average, with relatively few points below the zero line. This difference is in the right direction to be caused by sampling error. The bow pump intake is actually at about 1.5 m depth,

and thus, in waters where there is significant near-surface salinity gradient, the CTD values for 2 m, averaged from 1.5 m to 2.5 m, would be higher. The cluster of points in figure 2b near 28 psu and -1 salinity difference appears to be due to a CTD malfunction on August 10, 1993.

Analytical Precision, Dissolved Inorganic Nutrients

Over the period October 1991 through December 1992, no consistent replication studies were done. However, re-analysis of the filtered nutrient sample was occasionally performed, usually to check a questionable reading for one of the five analyses. The readings for the analyses not in question were considered duplicate analyses. The pooled standard deviations of the duplicate analyses (Ku, 1969) were as follows: DRP, 0.03 μM ($n = 10$); DSi, 0.94 μM ($n = 10$); N+N, 0.27 μM ($n = 11$); NO₂, 0.04 μM ($n = 11$); NH₃, 0.03 μM ($n = 8$). The coefficients of variation for these are: DRP, 0.4 percent; DSi, 0.8 percent; N+N, 1.0 percent, NO₂, 3.8 percent, and NH₄₊, 0.6 percent.

Between January and November of 1993, a regular program of replication was performed which involved duplicate filtrations from the bulk sample aboard the research vessel, and sometimes re-analysis of previously analyzed samples in the laboratory. Each re-analyses was generally within 4 hours of the original analysis. The results are shown in table 3 for the re-analyzed samples and table 4 for the duplicate filtrations. With the exception of DRP, the data indicate that the filtration procedure is probably not a source of variation in the data. For DRP, on five of six cruises with more than 10 reanalyses, the pooled standard deviation for the duplicate filtrations was larger than that for the reanalyzed samples. However, even in the worst situation, the coefficient of variation did not exceed 3 percent, and on 9 of the 11 cruises it was 1 percent or less.

Analytical Precision, Dissolved Organic Nutrients

All concentrations of DON and DOP are averages of the two single analyses of duplicate irradiated samples (TDN and TDP) minus their corresponding dissolved inorganic nutrient (DIN and DRP) concentrations. Thus, the precision of these numbers includes errors associated with the filtration, irradiation and decanting steps involved in the total dissolved nutrient analysis. Additionally, because the DON and DOP concentrations are calculated as the differences TDN - DIN and TDP - DRP, the precision of the DON and DOP is calculated as the square root of the sum of the squares of the precisions for the TDN and DIN, and TDP and DRP data sets.

For these data ($n = 65$), the pooled standard deviation for the total dissolved nutrients were: TDN, 0.55 μM and TDP, 0.02 μM . From the data in table 4, the standard deviation for DIN can be estimated (the square root of the sum of the squares of the means [weighted for the number of replicates] of the standard deviations for NH₄ and N+N) to be 0.20 μM , and that for DRP (the mean of the standard deviations) to be 0.02 μM . Thus, the standard deviation of the DON concentrations is estimated to be 0.59 μM , and that for DOP is estimated to be 0.03 μM .

Recoveries of known additions

One way to estimate the capability of an analytical technique to measure a dissolved substance is to add known amounts of the substance to samples. This procedure was performed on selected samples on two cruises, and the results, expressed as percentage of the added amount

that was recovered, are given in table 5. The data of February 24 are thought to represent the ability of the analytical techniques, whereas the data from January 26-27 were influenced by the process of familiarization with the specifics of a new procedure. For example, on the February cruise, all additions were done by weight, whereas in January, volumetric techniques were used.

Air leak in pumping system

Turbidity data for December 2, 1992 and August 10, 1993, are known to have been affected by an air leak in the pumping system that introduced bubbles into the turbidimeter. The data were not deleted from the report because they will be referred to in a later report on relations between turbidity and SPM concentrations for the period 1988-1993. The data for the cruises before and after these cruises appear to be free of this problem.

DATA TABLES

Table 6 summarizes measurements made, and identifies abbreviations and units used in the data tables. The data for northern San Francisco Bay are presented chronologically in tables 7 through 28, and the data from southern San Francisco Bay in tables 29 through 58. Notes at the end of each table give the specifics of the sampling for that cruise.

| | 36 | 13.0 | 3 | 100.6 | 99.5 | 96.5 | 100.6 | 100.8 |

Notes:

- a. Test not performed for ammonium on this date.
- b. No value due to an analytical problem.
- c. Addition was only 4.4 percent of ambient concentration.

Table 6. Summary of measurements, abbreviations, and units

| Measurement | Column Title | Units |
|-------------------------------|--------------|---|
| Local time | TIME | hours and minutes |
| Station | STA | -- |
| Depth | DEP | meters, m |
| Salinity (2 meter, CTD) | SAL | practical salinity units, scale of 1978, psu |
| Dissolved reactive phosphorus | DRP | microMolar, μM |
| Dissolved silica | DSi | microMolar, μM |
| Nitrate plus nitrite | N+N | microMolar, μM |
| Nitrite | NO2 | microMolar, μM |
| Ammonium | NH4 | microMolar, μM |
| Dissolved inorganic nitrogen | DIN | microMolar, μM |
| Dissolved organic nitrogen | DON | microMolar, μM |
| Dissolved organic phosphorus | DOP | microMolar, μM |
| Suspended particulate matter | SPM | milligrams per liter, mg/L |
| Turbidity | TURB | relative |
